

Qt + Elastic/Kibana: Prototype to Production

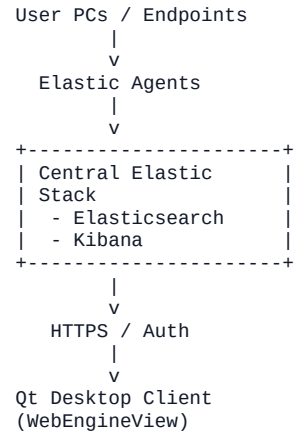

Current architecture, scalable direction, and the main production changes.

Current prototype

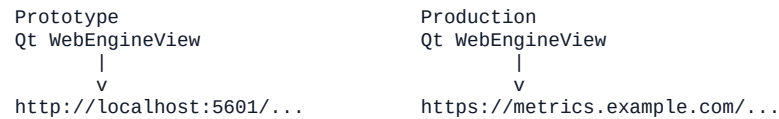

Everything runs locally. Elastic Agent collects host metrics, Elasticsearch stores them, Kibana builds the dashboard, and Qt embeds it.

Scalable / production direction

Elasticsearch and Kibana move to a shared secured deployment. Endpoints send metrics to that central backend instead of running the full stack locally.

Qt can keep embedding Kibana

The Qt client can keep WebEngineView. The dashboard URL changes from localhost to a secured central Kibana instance.

Before production

Now	Later
Local Docker stack	Central Elastic deployment
Hard-coded localhost URL	Configurable server URL
No access control	HTTPS + authentication + read-only access
Manual setup	Scripted or packaged setup
Basic embed	Loading/error states + tighter permissions
